7: Leeds E-4, 5 (1958) 1964 SS19 Yaruro SS19

social features reported, ideological features reported, and relations with other tribes mentioned. The card sets will be arranged by geographical location of the tribe so that for any given time period one may pull out all the sets and arrange the tribes in their spatial order. Thus for any time period a picture of the trait distributions, cultural-ecological conditions, inter-tribal socio-ecological relations, and acculturational-social contacts and events should be obtainable.

V

Though, to date, I have been concerned mainly with collecting bibliography and documentary materials rather than with their analysis, I should like to hazard several very tentative conclusions, or perhaps guesses, with respect to the ethnohistory of the llanos, and particularly of the Yaruro, based on the geographic, ethnographic, archeological, linguistic, and historical data known to me now. Some, however, are presented more as hypotheses for proof or disproof through continued research.

First, Petrullo's description is erroneous at least as respects the subsistence economy. Late Nineteenth Century travellers like Crévaux and Vela and several persons in this century mention horticulture. Still earlier reports go back to the earlier Eighteenth Century when missionaries speak of horticulture. Their reports apply to the Yaruro, Otomaco, Guahibo, and other groups. It has not yet been possible to decide whether they introduced or found horticulture among these peoples. Petrullo's error appears to have several explanations:

A) That he was incapacitated for several weeks by sore feet and was unable to travel about the land away from the rivers. In my experience, a careful criss-crossing of the land on foot is an absolute necessity if one is to know how these peoples carry on their subsistence activities. I have paced off with a pedometer the entire area used by the group I worked with. In the course of so doing I discovered all kinds of gardens, houses, and other evidences of their land use. These would not otherwise have been discovered by an observer nor mentioned by the Yaruro, since mainly what is physically present is, to them, worthy of mention.[10] I should say a great portion of my most important data came from such accidental discoveries made while walking about.

[10] I would stand at a certain spot in a garden and ask "Whose garden is this?" "Juan's." Then I might walk perhaps ten feet and say, "Juan keeps his garden well." "But this is not Juan's garden." "You just said that this was Juan's garden." "That was over there on the other side of that row of corn." This happened a number of times. I also asked once, "Is there female shamanism here?" "No." Several days later, a group from an neighboring village came to visit. After an all-night session of the *tou'be*, several women performed shamanistic rites. I said, "I thought you said there is no female shamanism here?" "There isn't anyone here [i. e. in our locality] who practices — these women are from upstream." The same cleaving to locus was observed with respect to time. I was told that Miguel was a shaman ("musico"). I said "Miguel, are you not a musico?" "I am not a musico. I cannot sing." A few weeks later, he was singing. I said,

B) Petrullo restricted his visits to the sand banks along and in the river, and, after his first arrival, most of his travelling was done on the streams. Gardens are never to be found on the sand banks and bars, but rather, usually, on the affluent creeks which are just above flood level of the rivers in the rainy season. Therefore he was not in a position to see the gardens which Le Besnerais later saw in the same area when he explored back from the river.

C) Petrullo was in the llanos in the dry season when the Yaruro move nearer the rivers both to secure a water supply as the water table lowers and to avail themselves of the much more plentiful and accessible river fauna[11] at a time when vegetable harvests are reduced because of drought. He was therefore observing dry-season subsistence — and perhaps only a part of it.

D) The probability that he observed only a part of the dry-season subsistence pattern in his area is reinforced by two considerations:

1) He reports the fact that 150 Yaruro had been massacred by Venezuelans a month before his arrival (p. 181). Their response under such circumstances is, as fast as possible, to get off the land that the Venezuelans want and to move to the rivers. I myself had occasion to observe such a diaspora, occurring in response to a smaller massacre. In view of this sort of response, it is likely, therefore, that Petrullo's group was living off river resources and away from their gardens at the time of his visit.

2) Maps indicate that in the lower part of the Capanaparo River, the flooding is greater and the number and size of side creeks suitable for horticulture is smaller than upstream on any of the large rivers. In other words, the available area for garden plots is much smaller, and riverine subsistence proportionately more important. Upriver, and more especially on the Sinaruco and on the middle and upper Cunaviche and Arauca rivers, there is much more tillable ground.

"I thought you said you could not sing and were not a musico?" "Yes, that was true last week when I had the grippe, but now my grippe is better I can be a musico again." And many similar examples of the extreme caution one needed to exercise regarding negative responses in order to be sure they were not merely descriptive of the place and moment. If Petrullo asked "Do you raise crops?", his informants would most likely have said, "No, we have no crops here", under the circumstances in which he found them.

[11] The river fauna is more plentiful and accessible in dry season because, first, it is more concentrated, and, second, it is more visible. During the wet, flooding season, fish, and other animals spread even into smaller streams and out upon the watery llanos — we caught a small piranha on the grassy, watercovered plain itself. On the plains, the fish are lost among the grasses and are virtually impossible to spear or shoot with bow and arrow. The river turbulence of the rainy season, meanwhile, has brought so much mud from further upstream that many of the rivers are opaque, especially in those parts of the llanos constructed of mud rather than sandy soils. Fish and the water reptiles and mammals are well-cloaked by the murky stream. The waters and the plains clear in the dry season so that the fish are concentrated in the limpid, grassless waters of the rivers, while land animals and riparian fauna are all crowded together near the banks in their search for food and water.
